Structured workflow rules for AI coding agents

Agent work gets hard to trust when the workflow only exists in chat.

Agent-Flow exists because capable agents still need local operating rules around Git, docs, review, and release.

Branch drift

A session can edit the wrong branch or collide with parallel work.

Weak handoff

A finished chat may leave no durable record of decisions or validation.

Hidden release risk

Open child worktrees can be bypassed when a parent branch is pushed.

Docs lag behind code

Behavior changes faster than maintainers can reconstruct it.

Agent-Flow is a local workflow kit, not another task database.

It installs shared rules, adapters, skills, scripts, and templates that make agent-assisted work repeatable across repos.

Shared instructions

AGENT-FLOW.md is canonical. AGENTS.md and CLAUDE.md point agents to the same rules.

Session scripts

Start, finish, reconcile, status, and release helpers manage worktrees with repo-local helpers.

Durable history

Every file-changing session leaves a devlog entry, decisions, and validation.

Release discipline

Review gates and push-readiness checks protect parent branches.

Install once, then every agent gets the same operating model.

Agent-Flow copies the shared setup into home-directory surfaces that Codex,

`./scripts/install.sh`

~/agent-flow

Shared rules, skills, scripts, docs, and templates.

~/codex

Codex adapter, AF skills, profiles, and AGENTS.md.

~/claude

Claude adapter and the same AF workflow context.

Every repo makes one choice: use Agent-Flow or opt out.

When a repo has no AF setup, file-changing work waits until init runs or the repo is marked disabled.

1

Run init in the repo

agent-flow/scripts/init-repo.sh creates config, adapters, docs, devlog, and helper scripts.

2

Choose branch rules

Pick integration branch, production target, optional staging, and push-readiness hook.

3

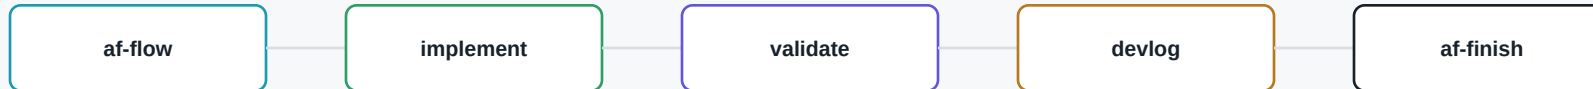

Opt out when needed

af-disable writes a local disabled config; af-enable reverses it or runs init.

af-disable | af-enable

Daily work stays fluid because the worktree is the durable session.

A Codex flow can continue across prompts while Git metadata, files, and the devlog keep the session grounded.

Do not finish after every prompt. Finish when you want to wrap, review, reconcile, merge, or switch direction.

Finish turns an open session into a merge-ready unit.

af-finish validates the work, checks docs and devlog, commits the session, and asks before merging.

Validation

Run the tests, builds, checks, or manual proof that fit the change.

Devlog

Record what changed, why, validation, proof, and risks.

Commit

Create a session commit from the isolated worktree.

Ask

Merge only after explicit approval.

```
scripts/finish-session.sh --merge
```

Release work uses a separate gate.

The daily loop stays light; release adds reconciliation, full review, optional security review, and PR preparation.

1

Reconcile open work

af-reconcile finds dirty, merged, unmanaged, and cleanup-ready worktrees.

2

Review the release diff

af-full-review runs the broad gate once, before protected branches.

3

Prepare the release path

af-release moves development through staging and main when configured.

4

Escalate security when needed

af-security-review is used for sensitive or configured release scopes.

Most days only need five concepts.

Specialist skills stay available for package, docs, audit, UI, and release work.

af-flow

af-status

af-review

af-reconcile

af-finish

Repo setup

af-enable, af-disable, af-pnpm

Documentation

af-docs, af-devlog, af-show

Campaigns

af-feature-audit, af-ui-audit, af-release

The payoff is trust you can inspect later.

Agent-Flow makes agent-assisted work safer to continue, review, merge, and explain because every session leaves a repo-local trail.

Use `agent-flow/scripts/init-repo.sh`

Use `af-flow` for this file-changing request.

Use `af-finish` when I am ready to wrap up.

**One related working session. One isolated
worktree. One devlog. Explicit review before
merge.**
